

LLM-Based Generation of BPMN Workflows From Textual Descriptions

NIVON Quentin, SALAÜN Gwen

What is BPMN?

- A **workflow-based notation** created in 2004 by the Business Process Management Initiative (BPMP) and the Object Management Group (OMG).
- It aims at **representing business processes** in a way that is **understandable for both experienced and novice users**.
- An **ISO/IEC standard** since version 2.0 in 2013.

- Companies are making use of the BPMN notation to **represent their business processes**.
- They **hire experts** to analyse and design the **most adequate BPMN process** according to their needs.
- These processes are often **syntactically/semantically incorrect**.

- What if you do not know **how to write BPMN**?
- What if you do not want to **spend time designing** your BPMN process graphically?
- How can you be sure that your BPMN process is **syntactically/semantically correct**?

General Solution

Internal Computations

General Solution

Internal Computations

First of all, an employee
CollectGoods. Then, the client
PayForDelivery while the
employee PrepareParcel.
Finally, the company can
either DeliverByCar or
DeliverByDrone (depending
on the distance for example)

Textual Representation of the Process

First of all, an employee CollectGoods. Then, the client PayForDelivery while the employee PrepareParcel. Finally, the company can either DeliverByCar or DeliverByDrone (depending on the distance for example)

**Textual Representation
of the Process**

**Large Language
Model (LLM)**

Overview of our Solution

First of all, an employee CollectGoods. Then, the client PayForDelivery while the employee PrepareParcel. Finally, the company can either DeliverByCar or DeliverByDrone (depending on the distance for example)

**Textual Representation
of the Process**

**Large Language
Model (LLM)**

- CollectGoods < (PayForDelivery, PrepareParcel)
- (PayForDelivery, PrepareParcel) < (DeliverByCar, DeliverByDrone)

$\langle E \rangle ::= \mathfrak{t} \mid (\langle E \rangle) \mid$
 $\langle E_1 \rangle \langle \text{op} \rangle \langle E_2 \rangle \mid (\langle E_1 \rangle)^*$
 $\langle \text{op} \rangle ::= ' \mid \& \mid '<' \mid ';$

**Expressions Following
an Internal Grammar**

BPMN Process

Dependency Graph

Abstract Syntax Trees

The user first has to write a **textual description** of the process-to-be.

First, the banker either CreateProfile (CP) for the user, or, if it is not needed, he RetrieveCustomerProfile (RCP) which triggers the system to perform the AnalyseCustomerProfile (ACP) task.

Then, the user executes the task ReceiveSupportDocuments (RSD) so that the system can start UpdateInfoRecords (UID) and perform a BackgroundVerification (BV).

If the verification finds missing or incorrect information, the system RequestAdditionalInfo (RAI) to the user, who has to ReceiveSupportDocuments (RSD) again.

Otherwise, the process ends with CreateAccount (CA).

The textual description is then **given to a (fine-tuned) LLM** (GPT 3.5 atm).

First, the banker either CreateProfile (CP) for the user, or, if it is not needed, he RetrieveCustomerProfile (RCP) which triggers the system to perform the AnalyseCustomerProfile (ACP) task. Then, the user executes the task ReceiveSupportDocuments (RSD) so that the system can start UpdateInfoRecords (UID) and perform a BackgroundVerification (BV). If the verification finds missing or incorrect information, the system RequestAdditionalInfo (RAI) to the user, who has to ReceiveSupportDocuments (RSD) again. Otherwise, the process ends with CreateAccount (CA).

The textual description is then **given to a (fine-tuned) LLM** (GPT 3.5 atm).

First, the banker either CreateProfile (CP) for the user, or, if it is not needed, he RetrieveCustomerProfile (RCP) which triggers the system to perform the AnalyseCustomerProfile (ACP) task. Then, the user executes the task ReceiveSupportDocuments (RSD) so that the system can start UpdateInfoRecords (UID) and perform a BackgroundVerification (BV). If the verification finds missing or incorrect information, the system RequestAdditionalInfo (RAI) to the user, who has to ReceiveSupportDocuments (RSD) again. Otherwise, the process ends with CreateAccount (CA).

The LLM processes the description and returns a **set of expressions** following an **internal grammar**.

$$\begin{aligned}\langle E \rangle &::= \mathbf{t} \quad | \quad (\langle E \rangle) \quad | \quad \langle E_1 \rangle \langle \text{op} \rangle \langle E_2 \rangle \quad | \quad (\langle E_1 \rangle)^* \\ \langle \text{op} \rangle &::= \text{'|'} \quad | \quad \text{'\&'} \quad | \quad \text{'<'} \quad | \quad \text{';'}\end{aligned}$$

Given our description, the LLM returns **three expressions**:

(RetrieveCustomerProfile < AnalyseCustomerProfile) | CreateProfile

Given our description, the LLM returns **three expressions**:

(RetrieveCustomerProfile < AnalyseCustomerProfile) | CreateProfile

(RetrieveCustomerProfile, AnalyseCustomerProfile, CreateProfile) <
(ReceiveSupportDocuments < (UpdateInfoRecords, BackgroundVerification))

Given our description, the LLM returns **three expressions**:

(RetrieveCustomerProfile < AnalyseCustomerProfile) | CreateProfile

(RetrieveCustomerProfile, AnalyseCustomerProfile, CreateProfile) <
(ReceiveSupportDocuments < (UpdateInfoRecords, BackgroundVerification))

(UpdateInfoRecords, BackgroundVerification) < ((RequestAdditionalInfo <
ReceiveSupportDocuments) | CreateAccount)

These expressions are then **mapped to** their corresponding **abstract syntax trees (ASTs)**.

The **sequential information** contained in the multiple ASTs is gathered to obtain a **cleaner** representation of it, called **dependency graph**.

Detailed Solution – Step 6

If the dependency graph **contains loops**, they are **analysed**, and all the **information needed to reconstruct** them is extracted.

Entry node(s) computation

Detailed Solution – Step 6

If the dependency graph **contains loops**, they are **analysed**, and all the **information needed to reconstruct** them is extracted.

Entry node(s) computation

Exit node(s) computation

Detailed Solution – Step 6

If the dependency graph **contains loops**, they are **analysed**, and all the **information needed to reconstruct** them is extracted.

Entry node(s) computation

Exit node(s) computation

Mandatory path(s) computation

Detailed Solution – Step 6

If the dependency graph **contains loops**, they are **analysed**, and all the **information needed to reconstruct** them is extracted.

Entry node(s) computation

Exit node(s) computation

Mandatory path(s) computation

Optional path(s) computation

Detailed Solution – Step 7

Once the loops have been retrieved, the **AST corresponding to the dependency graph** is built from the dependency graph.

Detailed Solution – Step 8

The **ultimate step** to obtain an AST containing all the information belonging to the original expressions consists in **inserting the choices**.

$(RCP < ACP) \mid CP$

$(RAI < RSD) \mid CA$

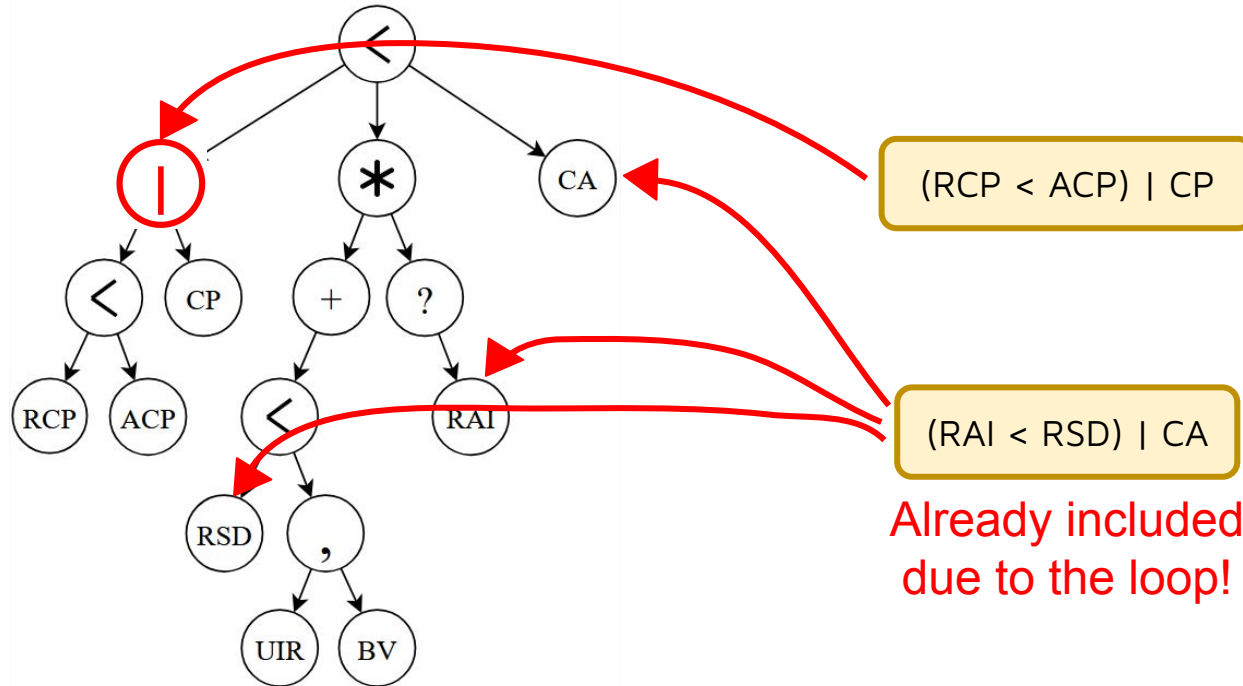

Detailed Solution – Step 8

The **ultimate step** to obtain an AST containing all the information belonging to the original expressions consists in **inserting the choices**.

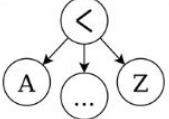

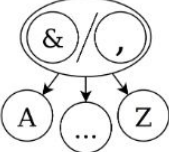

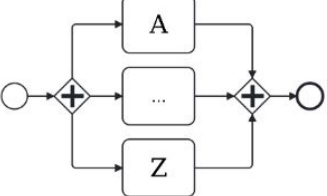

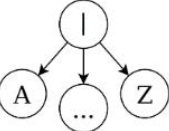

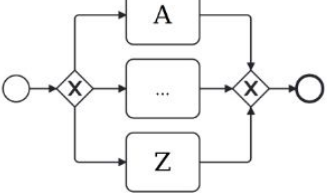

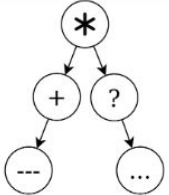

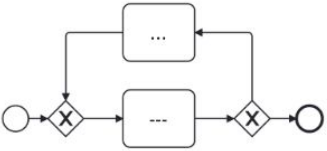

Detailed Solution – Step 8

The **ultimate step** to obtain an AST containing all the information belonging to the original expressions consists in **inserting the choices**.

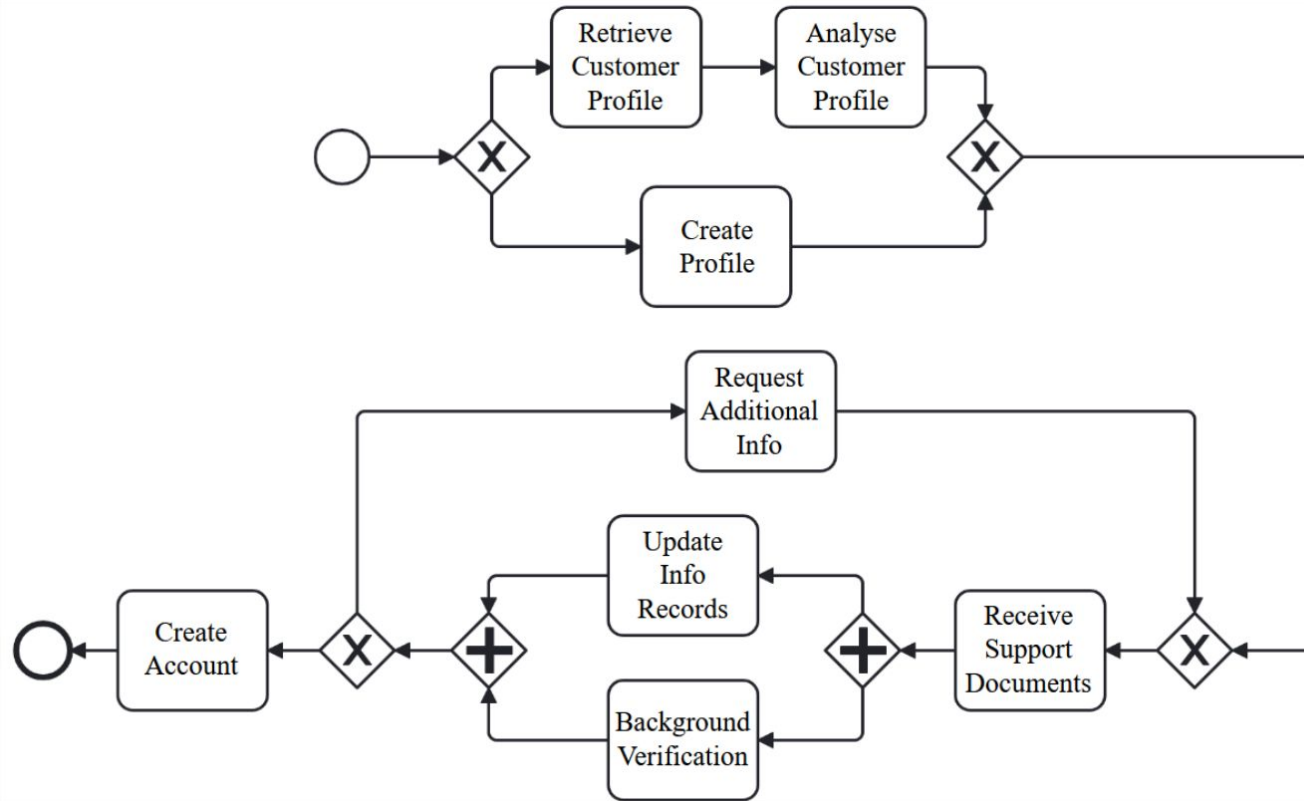

Now that the AST contains the choices, the **BPMN process is ready to be generated**.

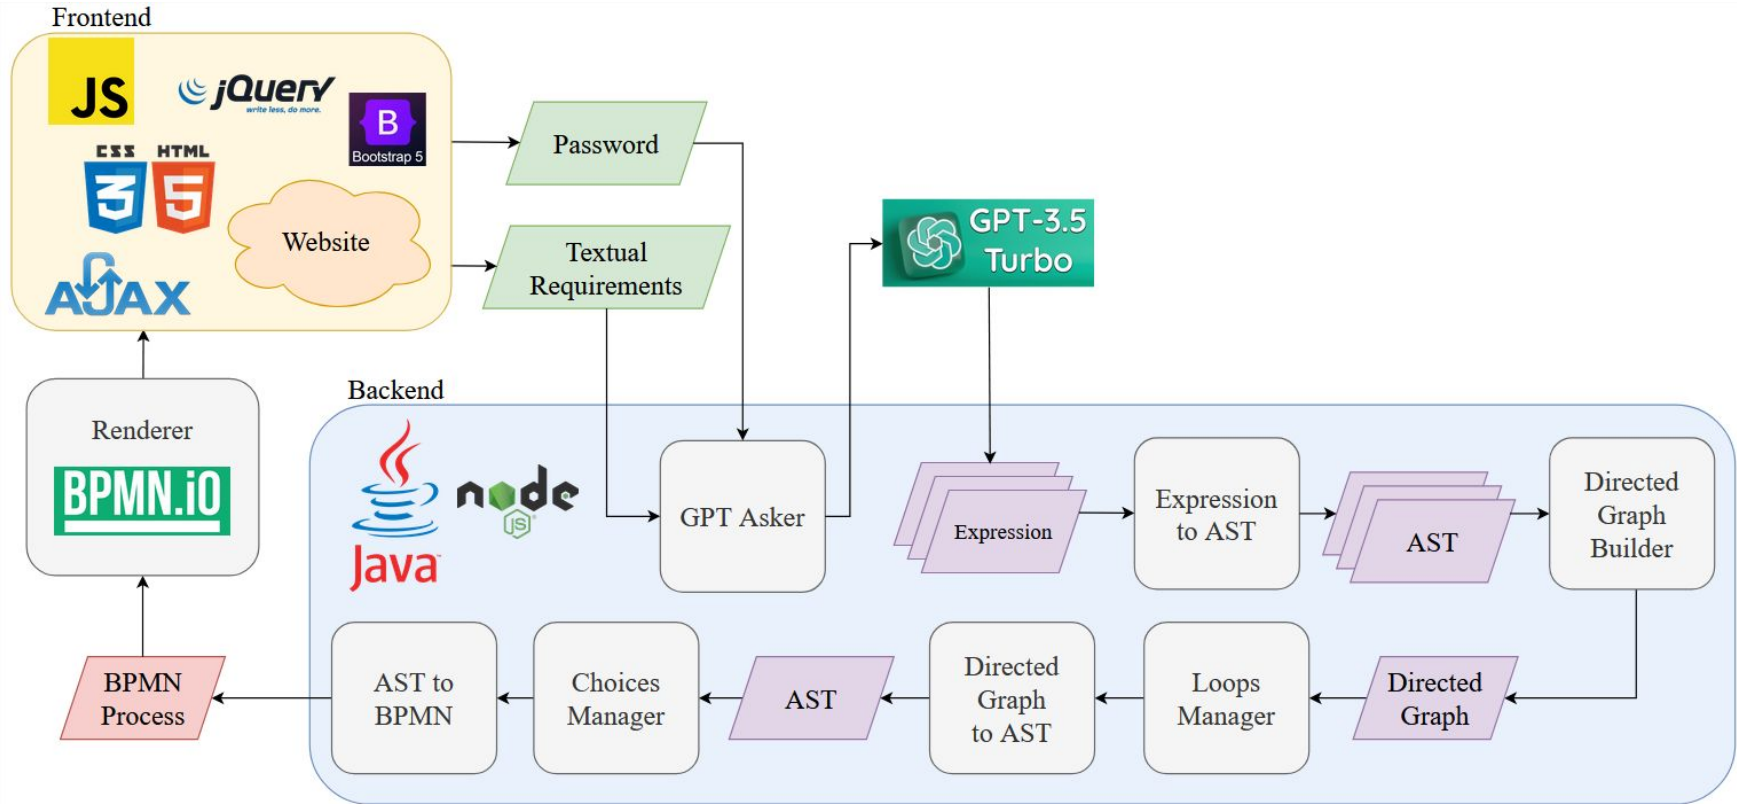

To do so, **patterns** are applied recursively to the merged AST, **starting from the deepest nodes** (leafs).

Pattern	AST	BPMN
(1) Sequential Pattern		
(2) Parallel Pattern		
(3) Choice Pattern		
(4) Loop Pattern		

Detailed Solution – Result

Tool – Presentation

Correct
processes

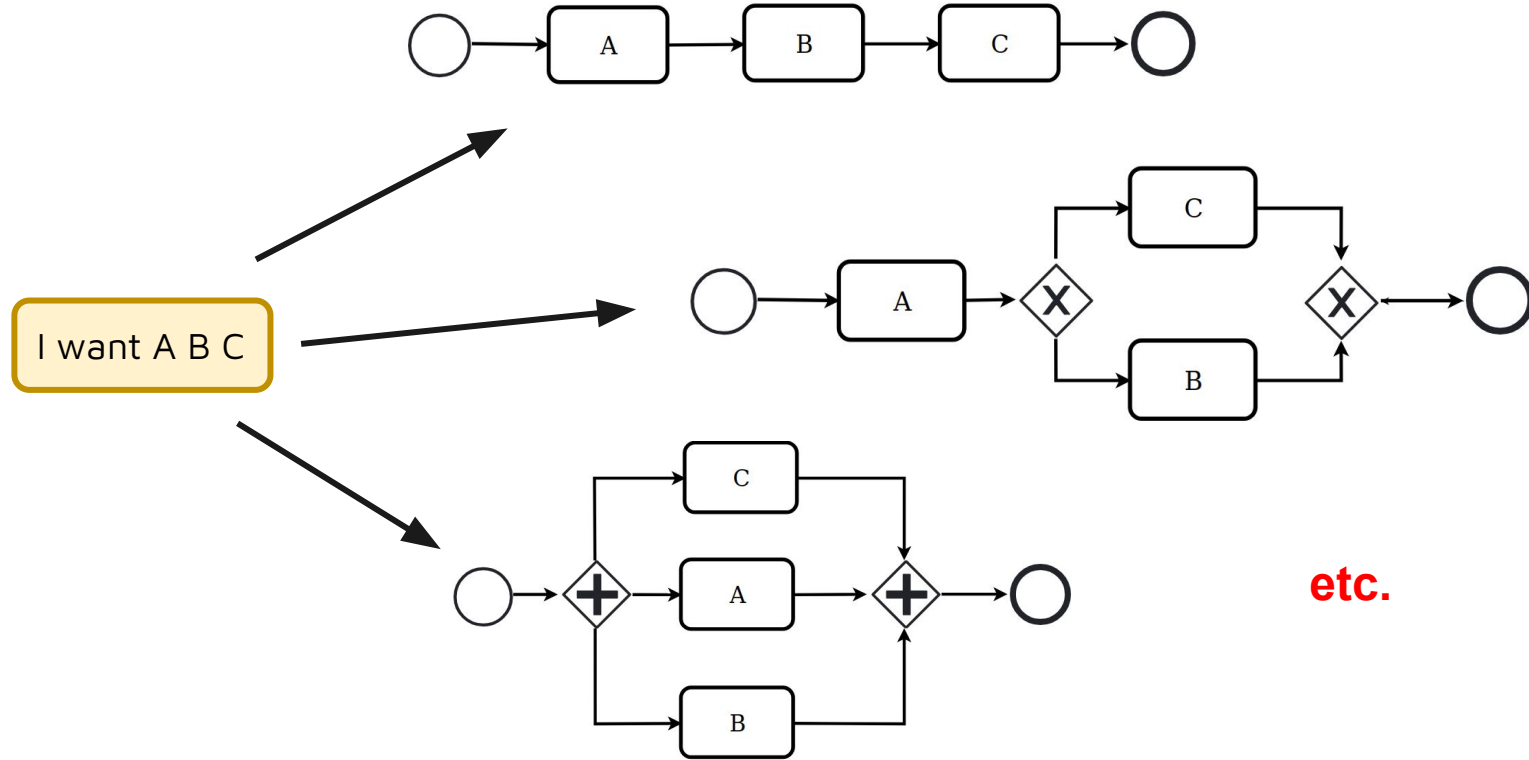

Ambiguous
processes

Incorrect
processes

Tool/Model	✓	?	✗	Avg. Exec. Time (s)
Our tool	78.5%	8%	13.5%	4.07
ProMoAI	50%	8.7%	41.2%	24.7
Gemini	32.2%	8.1%	59.7%	8.32
GPT-4-turbo	66.6%	21.1%	12.2%	19.2

An **ambiguous process** is a process that is **not incorrect** with regards to the description, but which **does not correspond to the expectations** of the experts.

The experiments conducted showed **14 incorrectly generated processes**. To understand the **source of this incorrect generation**, we **analysed the constraints** returned by GPT in these 14 cases.

	Missing constraint	Added constraint	Modified constraint
Total	9	17	6
Average	0.64	1.21	0.43

The last phase of these experiments consisted in **analysing the quality of the tool when the description is raw** (i.e., the tasks of the description are not named beforehand).

First, the banker either CreateProfile (CP) for the user, or, if it is not needed, he RetrieveCustomerProfile (RCP) which triggers the system to perform the AnalyseCustomerProfile (ACP) task.

First, the banker either creates a profile for the user, or, if it is not needed, he retrieves the customer profile which triggers the system to analyse it.

These experiments showed **a degradation of 16%** of the quality of the results when tasks are unnamed, for **three different reasons**:

- GPT may **introduce unnecessary tasks**
- GPT may **remove desired tasks**
- GPT may **not recognise that two distinct portions of text correspond to the same task**, thus creating two different tasks

In this work, we proposed an approach aiming at automatically designing **syntactically and semantically correct BPMN** processes from a **textual description** of the requirements.

We **already worked** on several **perspectives** of this work:

- Get rid of ASTs to allow more complex constructs (intricate loops/unbalanced gateways)
 - Formalise the transformation operations
 - Add new features (such as model checking of textual properties)
- } [TSE'25]
- } [FSE'25]

While some others are still **ongoing**:

- Adapt the description to (visual) process changes
- } David's work
